FOREWORD

The surface pressures of a highly swept delta winged model were measured at Mach numbers of 2, 3, and 4 in the Naval Surface Weapons Center Supersonic Tunnel No. 2 (NSWC T-2) using a commercial pressure measurement system. The tests were performed in May 1985. Surface pressure measurements are reported for 75 percent of the body length and the entire span of the wing for 0, 5, 10, and 15 degrees angle of attack and all roll angles from 0 to 360 degrees in 22.5-degree increments.

This work was sponsored by Mr. D. Hutchins of the Naval Air Systems Command (NAVAIR, AIR 320K) and Mr. L. Pasiuk of the Naval Sea Systems Command (NAVSEA R41 62). This document describes in detail the model design, the test apparatus, and the experimental techniques used for this test program. The authors wish to acknowledge Mr. G. D. Prats for suggestions on the use of the PSI system, Mr. D. W. Ausherman for feedback on past test programs, and Messrs. S. Cothran, Jr., and R. J. Marshall for their assistance in conducting the tests.

INTRODUCTION

In light of new missile system requirements, numerical methods for predicting aerodynamic performance have assumed an increased importance. Stringent requirements on missile radar cross section and range mandate the development of the capability to accurately predict the aerodynamics of unconventionally shaped missiles with blended inlets.

Traditional methods for predicting these aerodynamic characteristics are semi-empirical in nature and rely on an extensive data base for similar classes of missile shapes. Hence these predictive methods are often not applicable to new geometries of interest. Also, there is likely to be an increase in the use of ramjet propulsion which requires the ability to predict the inlet flow field. Such quantities cannot be determined by simple, semi-empirical prediction methods.

Numerical methods for calculating the aerodynamics of missiles are currently being developed. However, such methods need detailed experimental data for validation. Existing data generally is restricted to forces and moments with limited examples of surface pressure measurements¹. The typical missile configurations. The data generated by these

tests will be used to increase the level of understanding of the aerodynamic behavior of high lift-to-drag (L/D) vehicles at angles of attack in supersonic flows. In particular, it will be utilized to validate computational codes which are being developed to predict the flow field characteristics of such vehicles.

TEST FACILITY

The NSWC Supersonic Tunnel #2 (T-2) is a 16 x 16 inch cross section horizontal tunnel with an open jet test section and a model support system that has pitch, yaw and roll capability. The tunnel working medium is high pressure air which can be heated, via a steam heater, to temperatures from 175 to 225 degrees Fahrenheit . The tunnel is equipped with schlieren quality glass ports that permit a 16 x 24 inch viewing area. T-2 is capable of operating over a Mach number range from Mach 0.3 to Mach 5 with a supply pressure ranging from 0.5 to 15 atmospheres. This Mach range is provided by interchanging two-dimensional nozzles.

T-2 is capable of either blow-down or recirculating operation. For this test series, the tunnel was operated in a recirculating mode at Mach numbers of 2.02, 3.02 and 4.00 with nominal Reynolds numbers of $3.7 \times 10^6/\text{ft}$, $2.3 \times 10^6/\text{ft}$ and $1.5 \times 10^6/\text{ft}$, respectively ($p_0=1 \text{ atm}$).

MODEL DESCRIPTION

The basic model used for this test program consisted of a three caliber tangent ogive nose affixed to a two inch o.d., seven caliber cylindrical afterbody. It was designed as a split slotted body which could be used with any one of five wing configurations, shown in Figure 1. Also, a wing support allows for wing-alone testing.

The specific configuration tested is shown in Figure 2. The long delta wing is beveled so that a thin wing can be assumed in future calculations. The wing is positioned so that the leading edge starts at the aft part of the nose (six inches from the model nosetip). The total model wing span is six inches and the cross sectional thickness is 0.250 inches. The leading edge sweep angle is 77.5 degrees, the wing bevel angle is 75 degrees (as shown) and the root chord length is 9.02 inches. This wing contains 60 pressure taps, 58 of which are located on one half of the flat surface (see Figure 3). The body contains 91 pressure taps, 89 of which are clustered into one quarter of the body surface area. The two remaining taps in both the wing and the body yield flow symmetry data.

INSTRUMENTATION

Pressure measurements were made using a commercial system from Pressure Systems Incorporated (PSI). The PSI system consists of ten modules, each containing 16 pressure transducers. Each module is scanned electronically to acquire

its sixteen transducer output signals. The analog output signals are then transferred to the data acquisition and control unit (DACU), digitized and the results stored in the DACU RAM to be dumped to magnetic tape and reduced at a later time. Each pressure transducer was calibrated using a Stokes McLeod pressure gauge and a Barocel 1000 mm differential transducer. The accuracy of each PSI transducer was found to be within the specified accuracy; 0.25% of its full range (0.013 psi for 5 psi modules, 0.025 psi for 10 psi modules).

Tunnel conditions and model positions were recorded with a PSI random access mini millivolt (RAMM) analog-to-digital (A/D) converter. This A/D converter had an accuracy of 1.25 millivolts for a full-scale range of 500 millivolts.

TEST PROCEDURES

In preparation for a day of testing, the PSI system was brought on - line and an automatic pressure calibration sequence was initiated. The primary purpose of performing this simple three point calibration was to make available the ability to monitor the output of any one pressure transducer without collecting data. The transducers were then put through an eight point calibration to insure that the low pressure response characteristics of each transducer were defined. The calibration pressures ranged from 1 - 80 torr.

The RAMM-30 signals were also calibrated on a daily basis. A four point angle of attack calibration was made with alpha varying between 0 and 15 degrees. The roll angle calibration was made with five points from 0 to 360 degrees. The supply pressure was calibrated between 0 and 15 psi and the supply temperature was calibrated between 32 and 200 degrees Fahrenheit.

The model was positioned at 0 degree angle of attack before the tunnel was started. After the desired tunnel supply conditions were reached, data acquisition began. The model was first rolled to a position and then pitched through its series of angle of attack. A nominal 60 second delay for pressure equilibration was used between pitching and data acquisition for Mach 2 and 3. A 120 second delay was used at Mach 4. The model was always returned to 0 degree angle of attack prior to rolling to the next position. A list of run positions is given in Table 1.

DATA REDUCTION

The surface pressure measurements, the angle of attack, the roll angle, and the supply pressures and temperatures reported are averaged values of 50 data samples. The data rate at which these samples were collected is about 50 Hz. Each set of data was obtained in raw data counts and reduced using the calibration coefficients of the day. It was found that the transducer characteristics were best described by two straight lines, one for the lower pressures (1.1 - 5.0 torr) and one for the higher pressures (10.0 - 80.0 torr). In

the reduction of this pressure data, the point at which the two curves intersect was used as the criteria for determining which calibration curve would be used. The other data was reduced using standard reduction schemes.

RESULTS

Surface pressure data is presented in the appendix for each model run position (see Tables 2-9 for sample output). Each data set has been separated into two parts; body surface pressures and wing surface pressures. In the output, the pressure measured by each body pressure tap is given as $p(z/d, \theta)$, where z/d is the axial distance from the nosetip to the pressure tap and θ is the angular ray on which the pressure tap is located (see Figure 2). The pressure measured by each wing tap is given as $p(z/d, r/d)$ where z/d is the dimensionless axial distance from the nosetip to the pressure tap and r/d is the dimensionless distance from the model centerline to the pressure tap.

The model has four sets of symmetric pressure taps, two sets on the body and two on the wing. The values of each symmetric set are presented as two pressures separated by a comma (,). One should also note that the first, second and fourth axial positions of the wing matrix contain r/d coordinates which are not common to the remaining matrix. These tap locations are denoted with an asterisk(*), a plus

sign (+) and an exclamation point (!). The actual coordinates of these points are;

$$* \Rightarrow r/d = 0.5465$$

$$+ \Rightarrow r/d = 0.5745$$

$$! \Rightarrow r/d = 0.6850$$

In order to qualitatively illustrate the surface pressure data of the highly swept delta winged model, a commercial contour plotting routine based on a linear interpolation scheme was used. Sample results are given in Figures 4 - 7.

Schlieren photographs of selected runs are presented in Figures 8 and 9.

CONCLUSIONS

The surface pressures of a highly swept delta winged model were measured at Mach 2, 3 and 4 in the Naval Surface Weapons Center Supersonic Tunnel No. 2 (NSWC T-2) for a variety of model positions using a commercial pressure measurement system. The results of the test are listed in the appendix of this report.
